PREFACE

This project was completed under work unit 77191845 in support of HSC/YAR efforts to respond to ATC SON 003-88 and was a part of the initial operational test and evaluation of operational personnel abilities computer test hardware and software known as the Basic Attributes Test (BAT).

Appreciation is extended to SSgt Anthony Robertson, Sgt Maurice Kemp, and Sgt Rodolfo Ledesma for test administration support and to Sgt Keith Weekley for support in data processing and analyses. Appreciation also is extended to the personnel of the Human Systems Product Office (HSC/YAR) for their diligent efforts to help transition the BAT technology.

BASIC ATTRIBUTES TEST (BAT): OPERATIONAL PRE-IMPLEMENTATION ANALYSIS AND SCORE EQUATING

SUMMARY

The United States Air Force will implement a new pilot candidate selection system, beginning in 1993. Scores from a multiple aptitude paper-and-pencil test (Air Force Officer Qualifying Test or AFOQT), a computer-based test (Basic Attributes Test or BAT), and biographical information will be used to compute a pilot candidate selection composite score. The composite score derives from an equation designed to indicate probability of success in undergraduate pilot training (UPT). Pilot candidate selection boards will consider this score in combination with other types of information (e.g., medical, educational) to determine entry into UPT. The pilot candidate selection composite was developed using an experimental form of the BAT hardware and software. Experimental test systems are too few in number and difficult to maintain to support full-scale operational testing of Air Force pilot training applicants. The Air Force has developed and plans to field over 150 low-maintenance, operational test systems at several locations to test pilot training applicants. The purpose of this study was to determine differences and where differences existed to equate the experimental and operational BAT tests. The pre-implementation equating was necessary to (a) determine whether the tests measured the same psychological constructs as the experimental tests, (b) to compare score distributions of the two BAT tests, and (c) to develop equating tables for placing scores from operational tests on the experimental test metric. Equating was required so that scores from operational tests could be used in proposed pilot candidate selection equations developed on the experimental tests of the BAT.

Experimental and operational tests were administered to about 2,000 basic recruits. Analyses were performed at the test score and composite score level and several types of equatings were completed. Adjusted correlations between the experimental and operational BAT tests were acceptable and demonstrated construct validity. Differences in the shapes of the distributions (i.e., skewness, kurtosis) were observed for several of the scores between the two BAT forms. Several types of equatings (linear, equipercentile, smoothed equipercentile) were performed to develop conversion tables for use during implementation of operational tests. Scores will be renormed to the operational test metric and a new pilot candidate selection composite will be developed after a sufficient number of applicants have been tested and have completed UPT.

INTRODUCTION

Background

The Air Force plans to phase-in a new pilot candidate selection system in the near future. Scores from the Air Force Officer Qualifying Test (AFOQT, see Skinner & Ree, 1987), Basic Attributes Test (BAT, see Carretta, 1989, 1992), and biographical information will be used to compute a pilot candidate selection composite score. The AFOQT, though highly *g* loaded (Earles & Ree, 1991), is a paper-and-pencil test battery which

assesses five factorial ability domains: verbal, quantitative, spatial, perceptual speed, and aircrew interest/aptitude (Skinner & Ree, 1987). Fourteen of the 16 AFOQT subtests contribute to the Pilot and Navigator-Technical composites which are used for pilot candidate selection (U.S. Air Force, 1983). The BAT is a computer-based multiple aptitude test battery which measures individual differences in psychomotor skills, cognitive abilities, personality, and attitudes toward risk (Carretta, 1987, 1989). Several studies have demonstrated the incremental validity of BAT scores for predicting flying training performance (Carretta, 1989; Kantor & Carretta, 1988) and its robustness under cross-validation (Carretta, 1990). Additional pilot candidate selection factors include medical fitness, academic performance, aptitude test scores, and previous flying experience.

Purpose

The new pilot candidate selection composite, known as the Pilot Candidate Selection Method or PCSM, was developed using an experimental form of BAT hardware and software. The experimental BAT systems are too few in number and difficult to maintain to support full-scale operational testing of Air Force pilot training applicants. The Air Force selects pilot candidates from several sources including the Air Force Academy (AFA), Officer Training School (OTS), Reserve Officer Training Corps (ROTC), and active duty. The Air Force plans to field over 150 test systems at ROTC detachments, Military Enlistment Processing Stations, and other locations (i.e., AFA). The purpose of this study was to equate the experimental and operational test systems. The pre-implementation equating was necessary (a) to determine whether the production prototype tests measured the same psychological constructs as the experimental tests (i.e., construct validity), (b) to compare score distributions, and (c) to develop equating tables for placing scores from operational tests on the experimental test metric. Equivalency was required so that scores from the operational tests could be used in proposed Air Force pilot candidate selection equations developed on the experimental BAT system.

METHOD

Subjects

The subjects were 2,034 Air Force recruits with a median age of 19 years and were mostly White (84%), male (69%), and high school graduate or better (99%). All subjects were selected for training, in large part, on the basis of their Armed Services Vocational Aptitude Battery (ASVAB, see Earles & Ree, 1992; Ree, Mullins, Mathews, & Massey, 1982) scores, and educational achievements.

Apparatus

Both experimental and production BAT apparatuses consist of a microcomputer and monitor built into a carrel with a glare shield and side panels designed to eliminate distractions. Each subject responded to the tests by using, individually or in combination, a dual-axis control stick on the right side of the apparatus, a single axis control stick on the left side, and a specialized keypad in the center. The keypad included the number

keys 0 to 9, an ENABLE key in the center, and a bottom row with YES and NO keys and two others labeled S/L (for Same/Left responses) and D/R (for Different/Right responses).

Measures

The BAT was designed to measure individual differences in psychomotor skills, cognitive abilities, personality, and attitudes toward risk. The type of scores generated from these tests included tracking error/difficulty, response speed, response accuracy, and response choice. A test battery summary is provided in Table 1. A brief description of the tests follows and a more detailed description was provided by Carretta (1989, 1990).

Two-Hand Coordination. This pursuit tracking task was a measure of multilimb coordination (Fleishman, 1964). An airplane (target) moved in a fixed, elliptical pattern at a varying rate. The subject controlled the horizontal and vertical movement of a "gunsight" using the right (horizontal) and left (vertical) control sticks. The subject's task was to keep the gunsight on the target.

Complex Coordination. This stick and rudder, compensatory tracking task was an example of multilimb coordination and control precision (Fleishman, 1964). The dual-axis right control stick was used to control the horizontal and vertical movement of a cursor. The left control stick was used to control the left-right movement of a "rudder bar" at the base of the screen. The subject's task was to maintain the cursor (against a constant horizontal and vertical rate bias) centered on a large cross fixed at the center of the screen, while simultaneously centering the rudder bar at the base of the screen (also, against a constant rate bias).

Encoding Speed. This task assessed verbal processing efficiency and was adapted from a paradigm proposed by Posner and Mitchell (1967). The subject was presented simultaneously with two letters and required to make a same-different judgment about the letter pair. The complexity of the decision rule increased throughout the task.

Mental Rotation. This was a variation of a spatial transformation task (Shepard & Metzler, 1971). The subject was presented sequentially with two letters and required to make a same-different judgment. The letter pair consisted of either same or mirror images and the letters were either in the same orientation or rotated in relation to each other. A correct "different" judgment is associated with a mirror image pair and is not dependent on the relative rotation of the two letters.

Item Recognition. This measure of short-term memory was based on a task proposed by Sternberg (1966). A string of 1 to 6 digits was presented on the screen. The string was then removed, and after a brief delay, replaced by a single digit. The subject was instructed to remember the digit string and indicate whether the single digit was one of those presented in the digit string.

Table 1. Basic Attributes Test (BAT) Battery Summary

Test name	Length (min)	Attributes Measured	Scores
1. Test Battery Introduction	10	Biographical information	Age, handedness, previous flying experience, etc.
2. Two-Hand Coordination	10	Multilimb coordination, control precision	Tracking error
3. Complex-Coordination	10	Multilimb coordination, control precision	Tracking error
4. Encoding Speed	20	Verbal classification	Response time, response accuracy
5. Mental Rotation	25	Spatial transformation	Response time, response accuracy
6. Item Recognition	20	Short-term memory	Response time, response accuracy
7. Time Sharing	30	Higher-order tracking ability, learning rate and time sharing ability	Tracking difficulty, response time on secondary task
8. Self-Crediting Word Knowledge	10	Self-assessment ability, self-confidence	Response time, response accuracy, subject's prediction of own performance
9. Activities Interest Inventory	10	Attitudes toward risk	Response time, response choice

Note: Min means minutes.

Time Sharing. This test provided a measure of time sharing performance (North & Gopher, 1976). In the first 10 minutes of this test, the subject was required to keep a randomly moving "gunsight" on an airplane (target) using the right-hand control stick. In the next six minutes, the subject had to repeat the tracking task and simultaneously cancel digits which appeared at random intervals and locations on the screen. Digit cancellation was timed and consisted of pressing the same digit on the numeric keypad. The final three minutes of the test consisted of tracking only. Tracking difficulty was

varied by increasing or decreasing the control stick sensitivity as a function of the tracking error.

Self-Credibility, Word Knowledge. This was a vocabulary test where the subject was required to make predictions about his or her performance (i.e., self-confidence) prior to each group of items (Mullins, 1962). The subject had to predict if they would know the meaning of the next word. Items were multiple choice and used synonyms.

Activities Interest Inventory. This test was designed to measure the subject's attitudes toward risk-taking (Mullins, 1962). The subject was presented with 81 pairs of activities and was asked to choose between each pair. The activity pairs forced the subject to choose between activities that differed as to degree of threat (sometimes subtly, sometimes not).

Equating

Equating is the process by which test scores are made comparable by placing both on the same metric. Angoff (1971) provided this definition of equating.

A commonly accepted definition of equivalent scores is: Two scores, one on Form X and the other on Form Y (where X and Y measure the same function with the same degree of reliability), may be considered equivalent if their corresponding percentile ranks in any given group are equal (p. 563).

There are two usual types of equating derived from the commonly accepted definition. These are equipercentile equating and linear equating. If the two tests have the same distributional shape as demonstrated by equal measures of skewness and kurtosis, then linear equating may be conducted. Linear equating sets z-scores equal in both distributions and z-score equivalent raw scores are thereby equal. Equipercentile equating is the non-linear analogue (Angoff, 1971) which produces an area-transform on both distributions to make each rectilinear (i.e., percentiles). As percentiles are set equal (i.e., 95 on X to 95 on Y, 90 on X to 90 on Y, and so on) raw scores are set equal and thereby equated.

Because linear equating uses only two estimates, mean and standard deviation, it is desirable to use whenever possible. Equipercentile equating uses many estimates, one for each percentile and is more sample dependent and less stable. Also, equipercentile equating requires smoothing of the resultant equating functions. This was accomplished by first, second, and third order polynomial regressions which were constrained to be monotonic. These regression coefficients add to the number of estimates and the instability of equipercentile equating. When operational and experimental tests had approximately the same skewness and kurtosis, linear equating was used; otherwise, equipercentile equating was used.

Procedures

The BAT was administered on the 11th day of basic military training and the subjects were told that the test scores were being collected for experimental purposes only. In accordance with the Privacy Act, all subjects were given the opportunity to decline participation; none did.

The eight-test BAT battery, including breaks between tests to reduce physical and mental fatigue, requires about 2-hours, 40 minutes to complete. As subjects needed to test twice on the battery to estimate retest reliability, total testing time for the eight-test battery would have been about 5.5 hours. To accommodate time constraints and minimize subject fatigue effects, the eight tests were divided into two, four-test batteries.

Battery A consisted of a test-battery introduction and the first four tests described in Table 1 (Two-Hand Coordination, Complex Coordination, Encoding Speed, and Mental Rotation). Battery B consisted of the introduction and last four tests (Item Recognition, Time Sharing, Self-Crediting Word Knowledge, and Activities Interest Inventory). Subjects were assigned to one of eight test conditions based on test battery content (Battery A or Battery B) and test apparatus (experimental twice, experimental-operational, operational-experimental, or operational twice). Reliability was estimated by testing twice on either the experimental or operational battery. The number of subjects by battery and test condition is shown in Table 2. The research design used randomly equivalent groups (Campbell & Stanley, 1966).

Table 2. Number of Subjects by Battery and Test Condition

Battery	Test Condition	N	
A	experimental-experimental (exp-exp)	(347)	317
	experimental-operational (exp-op)	(234)	214
	operational-experimental (op-exp)	(241)	210
	operational-operational (op-op)	(209)	198
B	experimental-experimental (exp-exp)	(435)	402
	experimental-operational (exp-op)	(264)	233
	operational-experimental (op-exp)	(267)	233
	operational-operational (op-op)	(247)	227
Totals		(2,244)	2,034

Note: Number of subjects column reflects sample size (before) and after removal of missing data and outliers.

Analyses

Analyses were performed at the test score level and included descriptive statistics of the scores, t-tests between the means, F-tests between the variances, chi-square tests of the distributions, and correlations between the scores.

Correlations between tests from experimental and operational apparatuses were adjusted for unreliability using the formula (Stanley, 1971):

$$\text{Adjusted } r_{eo} = \frac{r_{eo}}{\sqrt{r_{ee'}r_{oo}}}$$

Where

r_{eo} = the correlation between experimental and operational BAT scores (combining data from the exp-op and op-exp conditions)

r_{ee} = the test-retest reliability of the experimental BAT (from the exp-exp condition)

r_{oo} = the test-retest reliability of the operational BAT (from the op-op condition)

The minimum acceptable adjusted correlation was set at .85. The measure of equating goodness (Braun & Holland, 1982) is how well the new test, *after equating*, has replicated the distributional shape of the old test. This was investigated and evaluated in this study, using the chi-square goodness-of-fit statistics.

To determine equivalence of means, variances, and distributional shapes, *t*-tests, *F*-tests, and chi-square tests were computed, respectively. The $p < .05$ Type I error rate was used on all observed data. No corrected correlations were tested.

Several of the test scores are measured in very small and precise increments (e.g., tracking error in pixels, response times in milliseconds). Each subject could potentially receive a unique value for these scores leading to several hundred values which would make it very difficult to equate the forms. To reduce the number of unique values, score intervals dependent on the units of the measures, were created before performing the equatings.

RESULTS

Descriptive Measures

Examination of descriptive statistics revealed several subjects with either missing or extreme values for one or more scores. Subjects with missing data were removed from the samples. Scores of extreme values (i.e., more than three standard deviations from the mean) were reviewed on a subject-by-subject basis. Those whose score profile suggested poor performance due to carelessness or lack of motivation were removed (Ree, Mathews, Mullins, & Massey, 1982).

Comparisons of "first test" scores (Table 3) from the experimental and operational batteries revealed several differences in score means (t-tests), variances (F-tests), and distribution shape (chi-square tests). When mean differences occurred, with the exception of Two-Hand Coordination vertical tracking error, the BAT test on the operational system was easier.

Table 3. Summary of Comparisons of Score Means, Variances, and Distribution Shape Between Experimental and Operational BAT Systems

Notes. 1. The sample sizes for the Battery A tests (Two-Hand Coordination, Complex Coordination Encoding Speed, and Mental Rotation) were 531 for the experimental (reference) group and 408 for the operational group.

2. The sample sizes for the Battery B tests (Item Recognition, Time Sharing, Self-Crediting Word Knowledge, and Activities Interest Inventory) were 635 for the experimental (reference) group and 460 for the operational group.

3. * $p < .05$.

Adjusted correlations, presented in the last column of Table 4, demonstrated an acceptable level of agreement between scores generated from the experimental and operational systems.

Table 4. Correlations Between Experimental and Operational BAT Systems

Test Score	Test Condition			Adj. r_{eo}

Activities Interest Inventory				
Avg. RT	.635	.673	.542	.829
Response Choice	.954	.937	.966	1.000

Note. The column headings for the test conditions refer to the experimental-experimental (Exp-Exp), operational-operational (Op-Op) groups, and the combined groups experimental-operational (Exp-Op) and operational-experimental (Op-Exp).

Measurement equivalency was confirmed. The two scores with adjusted correlations below the target value of .85 (Item Recognition - % correct, .839 and Activities Interest Inventory - Avg RT, .829) were above the lower limit of the 95% confidence interval around the .85 target correlation.

Equating

Subjects tested on the experimental apparatus during the first administration (experimental-experimental or experimental-operational) served as the anchor group during equating. This placed scores from the operational tests on the experimental form metric.

Several equating methods were compared to determine the most appropriate method for each test. The first equating decision was between linear (or z-score) equating and equipercentile equating. If the distributional shapes for both tests, experimental and operational, were about the same, linear equating was selected. Linear equating was desired as it requires the estimation of only means and standard deviations of the distribution. Equipercentile equating requires estimation of numerous percentile points. The more estimates from any set of data the less the reliability of each estimate.

The similarity of distributional shapes was determined by comparing the indexes of skewness and kurtosis for each distribution. Because large samples frequently lead to rejection of statistical hypotheses when no practical differences exist, any difference in skewness or any difference in kurtosis less than .15 was deemed to be of no practical significance. When differences below .15 were observed, the tests were equated with linear methods.

If differences in distributional shapes occurred, equipercentile methods were evaluated to determine the most appropriate smoothing for the curvilinear equating line. Smoothing was by the use of first (linear), second (quadratic), and third (cubic) degree polynomial regressions. The standard error of estimate (SEE) of the polynomial regression smoothing was used as a goodness-of-fit measure to compare the first, second, and third degree smoothings. For example, if one smoothing method such as the second degree provided a substantially smaller SEE than the first degree polynomial, the second degree polynomial was chosen as the smoothing method. All three polynomial smoothings were evaluated for all equipercentile equatings. When two smoothing polynomials differed little, the lower degree was chosen to minimize the number of parameters estimated, thereby enhancing robustness of the equating. Table 5 provides the SEE values for each of the polynomial smoothing methods applied to the equipercentile equatings.

Results were mixed. For the psychomotor tests (Two-Hand Coordination and Complex Coordination), the cubic polynomial smoothing method produced the best results for four of the five tracking error scores. Linear equating was chosen for the vertical tracking score from Two-Hand Coordination. Quadratic polynomial smoothing was chosen for the Psychomotor composite which is a unit weighted composite of the psychomotor scores.

Linear equating was considered the best method for the remaining scores, with the exception of Activities Interest Inventory response time (equipercentile-quadratic). The equating tables in the Appendix convert the scores from the operational test to the raw score based on the experimental test metric.

Table 5. Standard Error of Estimate for Linear, Quadratic, and Cubic Smoothing of Equipercentile Equatings

Use of the operational test is scheduled for the near future. Test scores will be renormed to the operational metric and a new pilot candidate selection equation will be developed after a sufficient number of applicants have been tested and have completed training.

DISCUSSION

The goals of this study were to determine the measurement equivalence (i.e., construct validity) of the operational tests and to derive scores on the operational tests that were comparable to scores on the experimental tests. Adjusted correlations between the experimental and operational tests were acceptable (i.e., the two forms of the tests measured the same construct). Differences in the shapes of the score distributions made it necessary to develop equating tables to convert scores from the operational tests to the experimental metric. Doing so made it appropriate to use scores from the operational tests in a pilot candidate selection model developed using the experimental tests. The differences in the scores between the experimental and operational apparatus were noteworthy. Despite assurances that the operational hardware and software would emulate the experimental hardware and software exactly, substantial differences were observed in scores. No assumptions of equivalence should be made when rehosting the same computer test software in different software and hardware environments. Evaluation of the effects of hardware and software on test performance is always recommended.
